

Space Exploration

Space exploration is the investigation of outer space using telescopes, satellites, probes, and human spaceflight missions. Over the past decades, space agencies have made significant discoveries about planets, stars, galaxies, and the origins of the universe.

Modern missions focus on Mars exploration, lunar research, asteroid studies, and deep-space observation. Scientists are particularly interested in determining whether life exists beyond Earth.

Technological advancements in reusable rockets, satellite communication, and artificial intelligence have reduced the cost of space missions. Private aerospace companies are also contributing to innovation in commercial space travel.

Future goals include establishing lunar bases, sending humans to Mars, and developing sustainable space habitats for long-duration missions.
